# Introduction to Java (cs2514) Lecture 13 & 14: Generics

M. R. C. van Dongen

March 12, 2018

### Outline

- These lectures study generic classes.
  - ☐ Generic classes help us detect certain kinds of errors.
  - They remove the need for certain run-time checks.
  - They also allow class-reuse for specialised versions of the classes.
- This lecture is based on [Naftalin, and Wadler 2009].
- At the end we shall implement a generic linked list class.
- Some of this lecture is based on the Java API documentation.

About this Document

- Many applications require collections of type-T objects.
- $\blacksquare$  Program manipulates a collection, C, using objects of type T.
- $\blacksquare$  To maximise re-use, C is implemented as collection of Object.
- $\square$  Since Object is a superclass of T:
  - $\blacksquare$  The compiler cannot assume *C* consists of type *T* objects.
  - $\blacksquare$  Run-time errors may occur when taking things from C.
  - Run-time checks have to be added: performance degradation.
- It would be nicer if we could tell the compiler:
  - $\blacksquare$  Trust me, all object in C are instances of (subclasses of) T.
    - This would help us detect/fix errors at compile time.
    - This would avoid errors at runtime.
    - This would increase efficiency.

## Solution: Generic Types

- A generic class depends on one or several type parameters:
  - ☐ A list with instances of the same class,
  - A binary tree with instances of the same class,
  - ...
- □ Instances of generic classes must have specific types:
  - A list of JButton objects,
  - ☐ A binary tree of Integer objects,
  - ...
- ☐ Generic types are used in combination with *collections*.
  - □ Lets you add objects to/remove objects from the collection.
- Java collection classes are all implemented as generic classes.
- ☐ If a generic class, G, is parameterised over a type, T.
  - You write G<T>.
- It guarantees that all objects "in" G have the same type: T.
  - Allows programmer to state what's in the collection.
  - Allows the compiler to detect errors at compile time.
  - □ They eliminate the need for adding certain runtime checks.
  - They avoid runtime errors.
  - Avoids code duplication.

About this Document

- An important interface is Comparable.
- A Comparable object can compare itself to other objects.
- $\hfill\Box$  To implement Comparable<T> you must override the method
  - ☐ int compareTo( T that ).
- □ compareTo() should implement deep comparison.
- □ Comparison depends on result of compareTo( that ):

Negative: this is less significant than that.

Positive: this is more significant than that.

Zero: this and that are equally significant.

## Substitution Principle

When Java expects a value of a given type, you may also provide a value of a subtype of that type.

```
public interface Collection<T> {
    ...
    public boolean addAll( Collection<? extends T> collection );
    ...
}
```

- dest.addAll( source ) adds all items from source to dest.
- □ Only makes sense if the things in source are subtypes of T.
- The spell ? in Collection<? extends T> is a wildcard.
  - ☐ It is any type (class/interface) extending T.
- So Collection<? extends T> collection guarantees that:
  - Any object in collection is-a T.
- Assume Sub is some subtype of some type Sup.
  - Then Collection<? extends Sup> is supertype of Collection<Sub>.

About this Document

We just studied the spell ? extends T.

□ It is for collections consisting of instances from subclasses of T.

■ The ? denotes any subclass of T.

It lets you safely get things from collections.

□ Collection<Sub> is a subtype of Collection<? extends Sup>.

## Java

```
final ArrayList<Integer> ints = new ArrayList<>( );
final ArrayList<? extends Number> nums = ints;
```

- Java also has a spell ? super T.
- It is for collections with instances of superclasses of T.
  - The ? denotes any superclass of T.
  - The spell? super T lets you safely put things into collections.
  - □ Collection<? super Sub> is a supertype of Collection<Sup>.

### Java

### Linked Lists

### Recursive Class Definition

- Java already has an interface called List, so we implement our lists as MyList instances.
- Each MyList instance has an attribute called nodes,
  - □ This attribute represents what's in the list.
  - ☐ If the list is empty, the value of nodes is null.
  - Otherwise, nodes represents a non-empty list.
  - Each Link instance represents a non-empty lists.
- Each Link instance has a *head* and a *tail* attribute.
- The *head* is the first item in the list.
- The tail represents the remaining items in the list.

```
Java
```

```
public class MyList { private Link nodes; ... }
```

About this Document

- We shall sort our list using the QuickSort algorithm.
- We do not have an array, but we use the same idea:

Base case: If the list is empty then it is already sorted. Recursion: Otherwise:

- 1 The list is not empty.
- 2 Let head be the head of the list.
- 3 Partition the tail of the list into two lists leq and gt:
  - leg contains members less than or equal to head.
  - gt contains members greater than head.
- 4 Sort leq and gt.
- 5 Add head to the front of gt. Let gtExtended be this list.
- 6 Append leq and gtExtended.

About this Document

■ Generalised for loops work for any kind of array.

Generalised for loops work for any kind of array

Also works for collection classes.

- But ArrayLists aren't arrays.
- So how does this work?

■ To implement the interface you only have to do one thing:

Override Iterator iterator().

```
Tava
final ArrayList<String> strings = (magic);
for (String str : strings) {
    // Use string.
```

```
Java
final ArrayList<String> strings = (magic);
final Iterator<String> iterator = strings.iterator();
while (iterator.hasNext( )) {
    String string = iterator.next( );
    // Use string.
```
